COMPOSER: Visual Analysis of Patient Outcomes

Jennifer Rogers, Darrel Brodke, Rachel Hess, Nicholas Spina, and Alexander Lex

This project emerged from a collaboration with four medical researchers from the Orthopaedic Research Center and the Department of Population Health Sciences at the University of Utah, who are currently investigating the use of PROMIS scores as a measure of patient well-being and progression of physical function following various procedures for spinal ailments.

**Domain Requirements:**

- **Define meaningful cohorts of patients.** The clinicians need to be able to identify groups of people based on various characteristics, such as demographics and medical histories.
- **Compare the outcomes of different cohorts.** Once cohorts are identified, clinicians want to compare how they respond to different treatments, or see if they have other conditions in common.
- **Normalize Physical Function Scores** in several ways to successfully analyze and compare cohort outcomes following an event, such as surgery.

**Domain Space, Motivation, & Requirements**

**Motivation:** Determining the best treatment options for patients involves an assessment of their medical histories and a comparison to similar patients. Such comparisons have relied on a physician’s memory of related prior cases, which can be influenced by cognitive biases.

**Design & Functionality**

1. **Cohort Definition**
   - **Cohort control panel:** Cohorts can be added, branched and deleted.
   - **Filter History:** All filters are applied to the selected cohort along with the distribution of patients in the cohort at each filter stage.
   - **Demographic Filters:** Cohorts can be defined by demographic attributes. Quantitative values such as BMI can be brushed to a range. Categorical values can be selected.
   - **Score & CPT Filters:** Cohorts can be further refined by constraints added to score count and presence/absence of a procedural code (CPT) used to indicate a given procedure in the EHR.

2. **Outcome Score Comparison**
   - **Dynamic Score Scales and Normalization:** Patient scores can be normalized to show score change relative to a procedure or treatment.
   - **Separation of Scores by Quantiles:** A cohort can be divided by quantities. We calculate these quantities by the average change in score over a customizable period of days following a given event.
   - **Aggregation of Scores:** Scores can be aggregated to be centered on the median of the data.
   - **Individual Patient CPT History View:** Patients procedure code histories can be viewed by selecting individual patients in the score chart.

3. **Separation of Scores by Quantiles**
   - Individual and aggregated scores, aligned by a surgery code, separated into and color coded by quantities.

4. **Aggregation of Scores**
   - Aggregated scores separated into quantities.
