Regulation of intercellular communication

- It is simple

  Electrically we evaluate gj or junction conductance

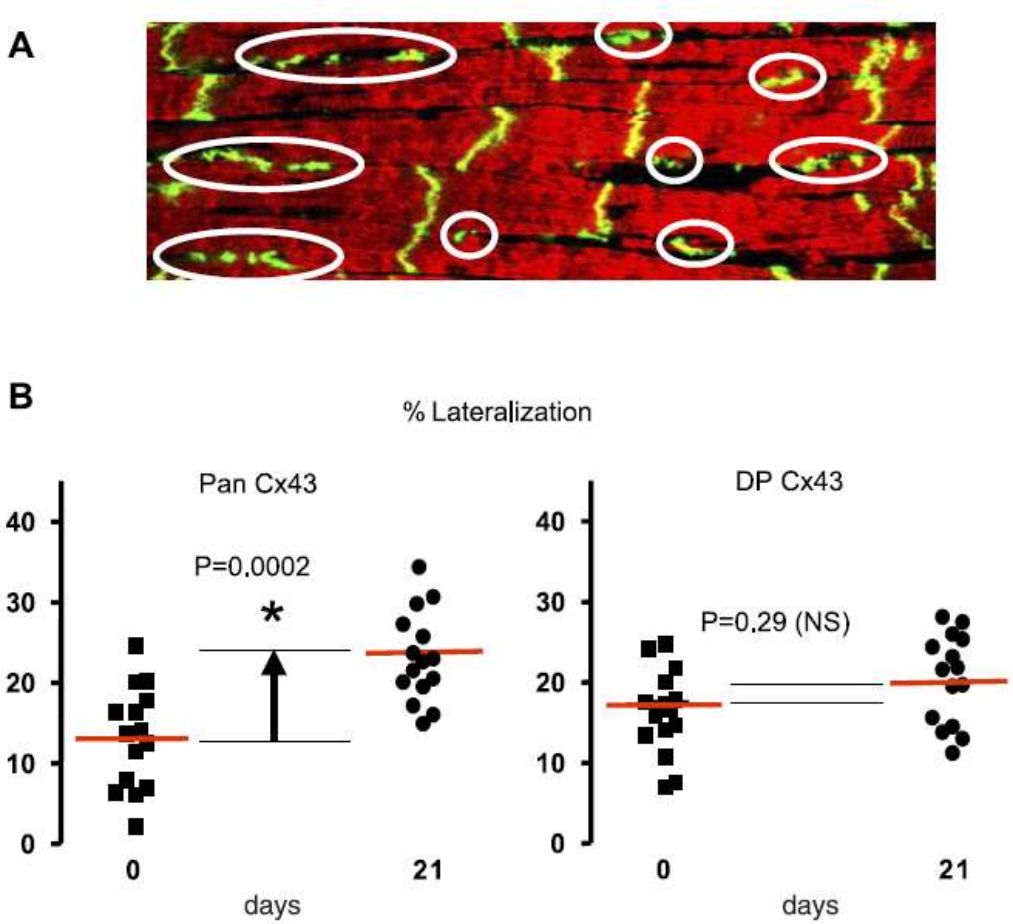
$$g_j = n * \gamma_j * Po$$

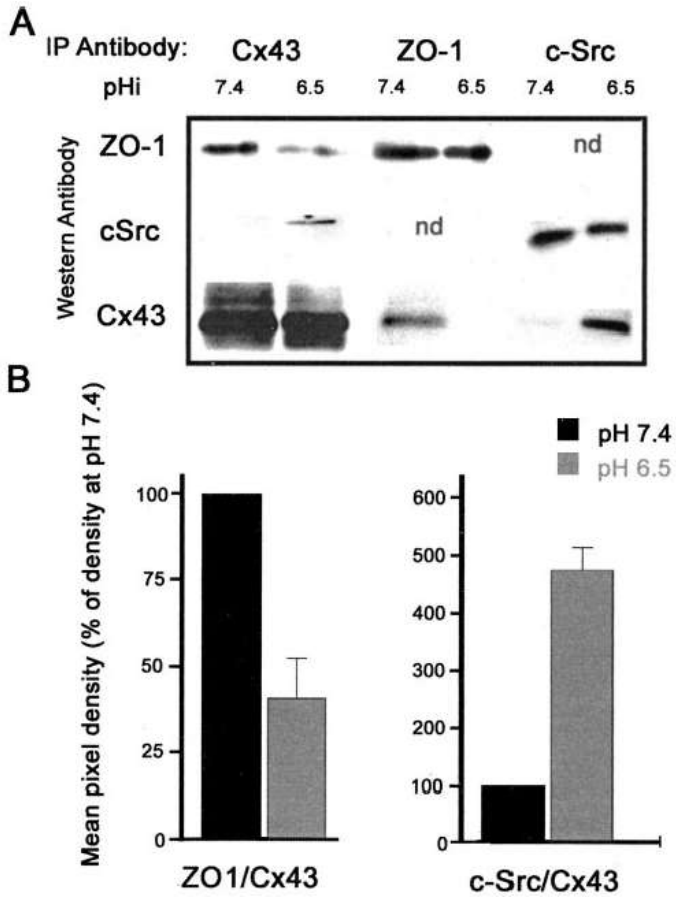
n = number of channels

γ_j = unitary conductance

Po = open probability

Remodeling (long term ischemia or heart failure)





Gating of gap junction channels

- Gating by voltage
  - Transjunctional and transmembrane
- Gating by intracellular pH
- Gating by protein phosphorylation

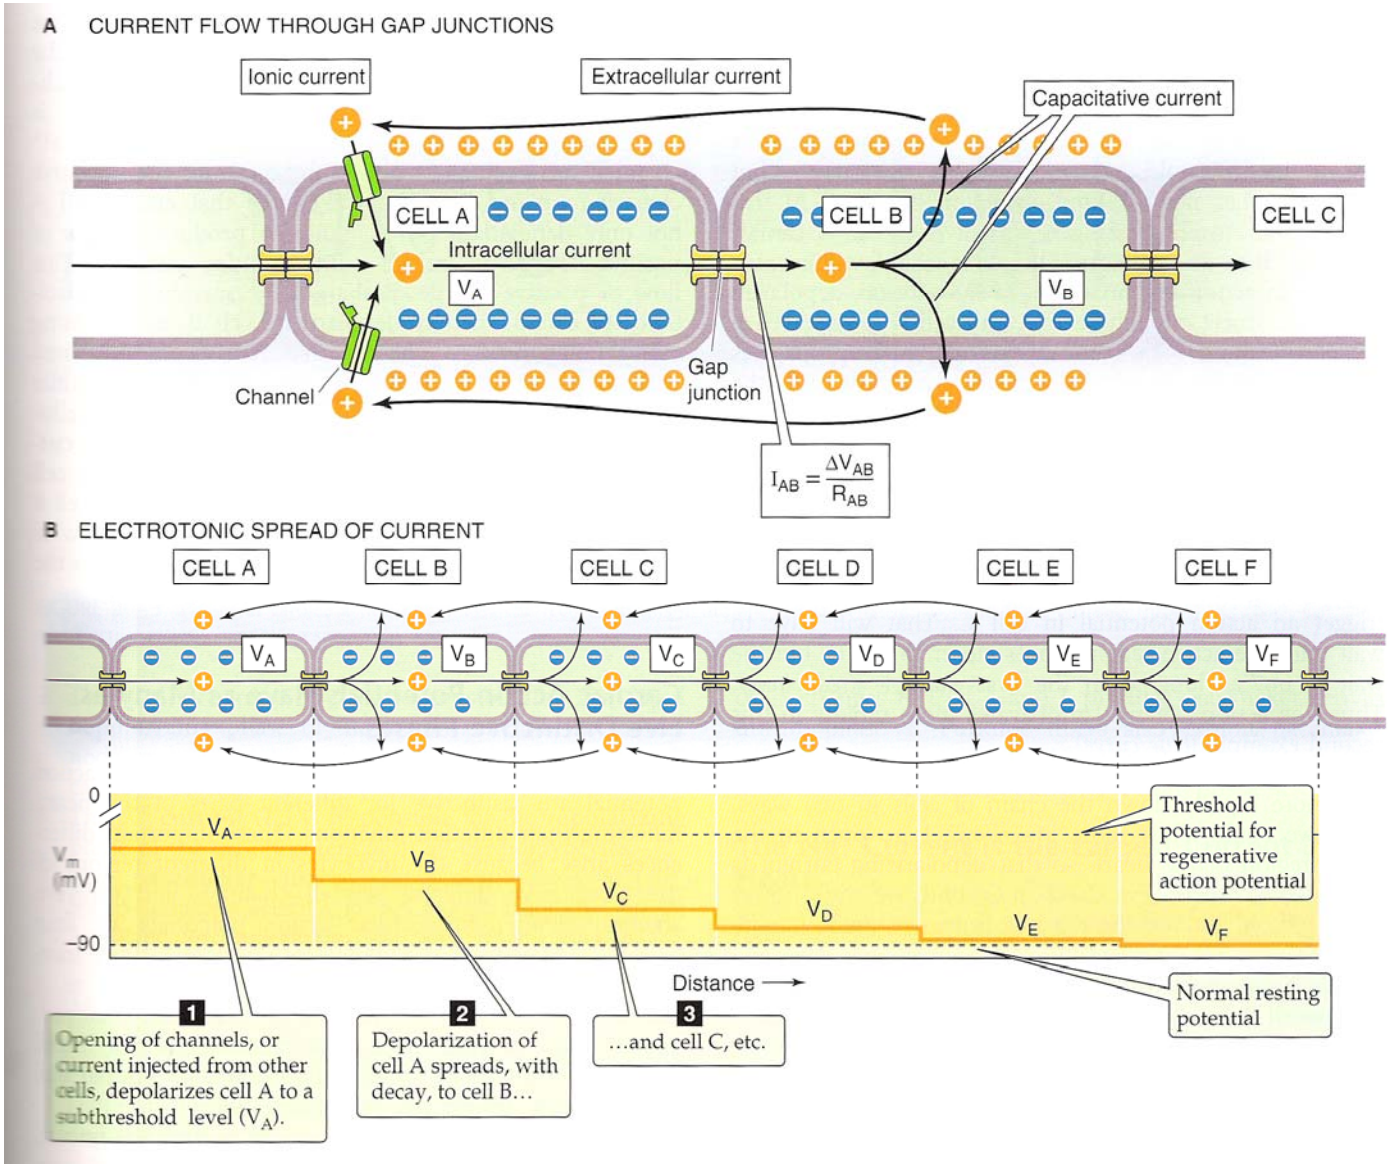
Electrotonic conduction in cardiac fibers



Gating by pH

The reduction of intracellular pH causes a reduction in the conductance of the junction (Gj/Gmax).

When the COOH tail is removed, there is no gating by pH.

If the COOH tail is co-expressed, the gating by pH is re-established.

Intra-molecular interactions rule pH gating for acidosis

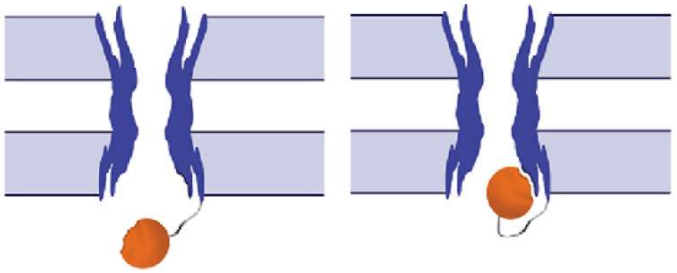

Fig. 1. Diagram illustrating the concept of a ball and chain model for chemical regulation of connexins. An intracellular flexible domain (the carboxyl terminal domain) acts as a gating particle. Under normal conditions, the gate is away from the pore. Under the appropriate stimulus, the gate would swing toward the mouth of the channel, bind to a "receptor" affiliated with the pore, and close (or modify) the channel.

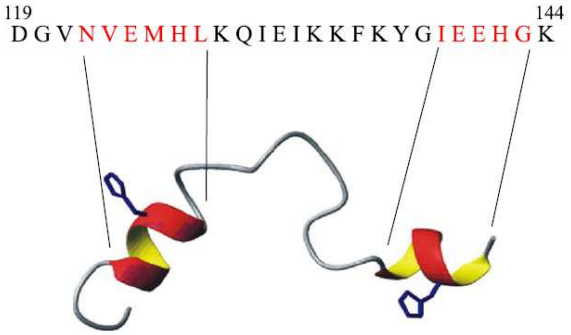

Fig. 6. Secondary structure of a peptide corresponding to amino acids 119–144 of Cx43, as solved by nuclear magnetic resonance. We propose that this structure acts as a receptor for the gating particle during chemical regulation of Cx43 channels.

Connexin26 channel at 3.5Å resolution
Details from the pore

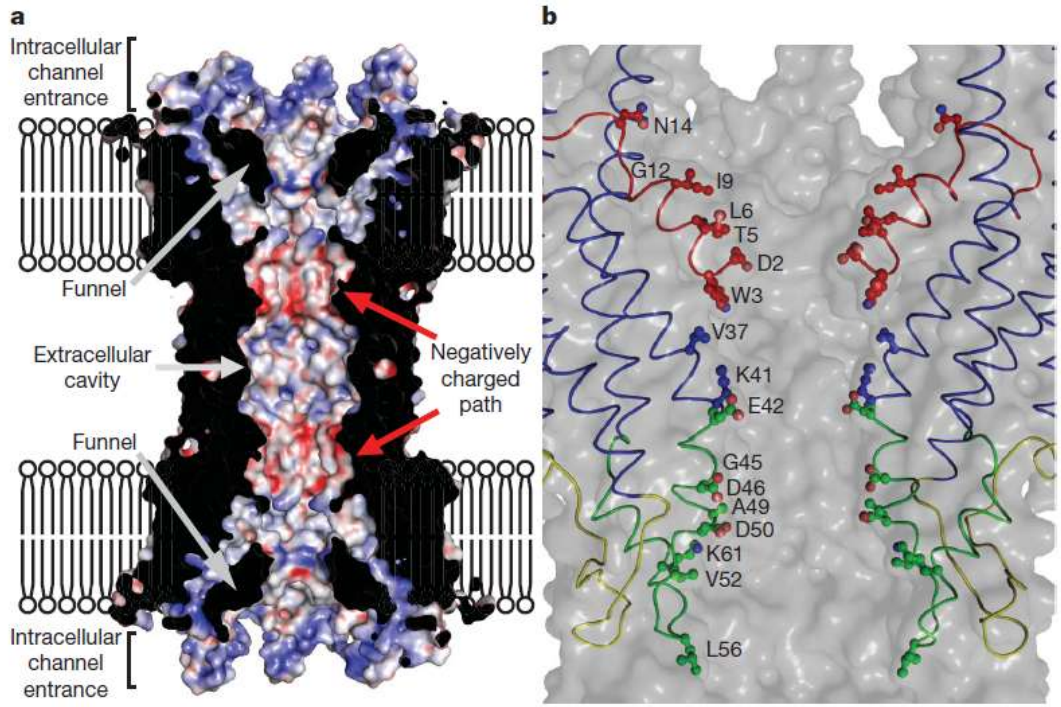

Figure 4 | Pore structure of the Cx26 gap junction channel. **a**, Vertical cross-section through the gap junction channel, showing the surface potential inside the channel. The channel features a wide cytoplasmic opening, which is restricted by the funnel structure, a negatively charged path and an extracellular cavity at the middle. Electrostatic surface potential of the Cx26 gap junction channel was calculated by the program APBS[43] as implemented in PyMOL under dielectric constants of 2.0 and 80.0 for protein and solvent regions, respectively. The displayed potentials range from −40 (red) to 40 (blue) kTe^{-1}. **b**, Pore-lining residues in a Cx26 gap junction channel. Side view of Cx26 gap junction channel pore; the main chain is depicted as a thin ribbon and side chains facing the pore as balls and sticks. For fine viewing, two subunits in the foreground are omitted in the surface representation and two further subunits in the background are omitted in the model depiction. The colouring is the same as in Fig. 3b.

Permeation modeling equations in a particle collision model

External Forces

$$F_{Electrostatic} = \frac{1}{4\pi\varepsilon_0}.\frac{q_1.q_2}{r^2}\left(\hat{r}_{12}\right)$$

$$F_{Brownian} = K_{Br}.\hat{v}$$

$$F_{EF} = qE$$

$$F = F_{Electrostatic} + F_{Brownian} + F_{EF} + F_{Misc}$$

Particle-Particle Interactions

$$c = \hat{n}\cdot\left(u_1 - u_2\right)$$

$$v_1 = u_1 - \left(\frac{m_2 c}{m_1 + m_2}\right)(1+e)\hat{n}$$

$$v_2 = u_2 - \left(\frac{m_1 c}{m_1 + m_2}\right)(1+e)\hat{n}$$

Wall- Particle interactions

$$\vec{v} = \left|\vec{u}\right|\left(\hat{u} - 2\hat{n}\left(\hat{n}\cdot\hat{u}\right)\right)$$

Particle Dynamics

Velocity

$$v = u + a\Delta t$$

Acceleration

$$a = \frac{F}{m}$$

Position

$$s = s_0 + u\Delta t + \frac{1}{2}a\Delta t^2$$

Conduction after infarction

- Myocardial infarction (MI) healing process includes revascularization and formation of scar tissue.
- Scar tissue is composed of fibroblast-like cells embedded in a collagen-fibrous matrix.
- Scar formation causes complex changes in the organization of cells in the infarcted area.

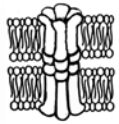
Summary

- Gap junction channels could be formed of distinct isomeric forms.
- Each isoform can form channels with unique gating for voltage and chemical agents.
- Permeability of gap junctions depends on the isoforms involved in the formation of channels and on the properties of the crossing-molecules.
- Heteromultimeric channels can become highly selective and are thought to be involved in various physiological and pathological processes.

Alonso P. Moreno
Connexin Lab
CVRTI U of Utah



- Heterotypic communication can alter channel selectivity and create a preferential flux direction of metabolites across gap junction. One of the mechanisms to explain this preferential flux could be based in differences in pore mouth and charge.

- Long standing electrophysiological phenomena related to the complex nature of electrograms in the infarct border region could be explained by changes in cardiac conduction due to hetero-cellular coupling.

- Studies related to this mechanism of conduction could significantly impact the interpretation of cardiac electrograms, increase the understanding of arrhythmia substrates, and make a significant contribution on the development of more guided approaches to arrhythmia treatment.
